The phytochemical investigation of Bakeridesia pickelii Monteiro led to the isolation of seven compounds: β-sitosterol, a mixture of stigmasterol-3-O-β-D-glucopyranoside and stigmasteryl-3-O-β-D-glucopyranoside, vanillic acid, p-coumaric acid, quercetin 3-O-β-D-glucopyranoside (isoquercitrin) and kaempferol-3-O-β-D-(6'-E-p-coumaroyl) glucopyranoside (tiliroside), which was isolated as the major component. Their structures were elucidated on the basis of spectroscopic data such as IR, 1H and 13C NMR, including two-dimensional techniques. Tiliroside relaxed the guinea-pig ileum pre-contracted with KCl 40 mM (EC50 = 9.5 ± 1.0 x 10 -5 M), acetylcholine 106 M (EC50 = 2.3 ± 0.9 x 106 M) or histamine 106 M (EC50 = 4.1 ± 1.0 x 106 M) in a concentration-dependent manner.

Keywords: malvaceae; Bakeridesia pickelii; relaxant activity.

INTRODUCTION

The Malvaceae family comprises about 243 genera and 4225 species in the new phylogenetic circumscription1. Members of this family are widespread in many regions of the world and particularly in tropical regions, mainly in South America1. Many species of Malvaceae are known for their different uses in folk medicine such as diuretic, in treatment of rheumatism, gastrointestinal disorders4, snakebites3 and asthma2. Antiinflammatory and antinociceptive effects have also been investigated2. Previous phytochemical investigations of Malvaceae species describe the isolation of fatty acids4-11, essential oils12, sesquiterpenoids of cadinene-type13, to which has been attributed an insecticide activity, sesquiterpenolactones14, triterpenes15 and flavonoids16,17, among many others compounds. Based on the great variety of natural compounds found in species of the Malvaceae family as well as their pharmacological properties, we chose Bakeridesia pickelii, an endemic and unstudied species of the Brazilian Northeast to accomplish our study.

This work describes the first phytochemical investigation of Bakeridesia pickelii and the relaxant activity of kaempferol-3-O-β-D-(6'-E-p-coumaroyl) glucopyranoside (tiliroside) on guinea-pig ileum.

EXPERIMENTAL

NMR and chromatographic procedures

NMR spectra (1H, 13C, HMQC, HMBC, COSY) were run on a Mercury Varian instrument operating at 200 MHz and 50 MHz for 1H and 13C, respectively. The NMR data were measured in CDCl3, CD3OD and pyridine-d and chemical shifts are expressed in ppm with reference to the solvent signal. Chromatography columns were performed on silica gel (Merck) and Sephadex LH-20 (Pharmacia, Uppsala-Sweden). The fractions were monitored by TLC analysis, using plates coated with silica gel 60F254 (Merck). The plates were developed with iodine, visualized under UV light (244 and 366 nm), and spraying with 5% FeCl3 reagent (for detection of glycosyl flavonoids).

Plant material

The aerial parts of B. pickelii were collected in May, 2002 in the Pico do Jabre, municipality of Maturéia in State of Paraíba, and identified by Dr. M. de F. Agra. The voucher specimen Agra et al. 5151 is deposited at the Herbarium Prof. Lauro Pires Xavier (JPB), Universidade Federal da Paraíba, Paraíba, Brazil.

Extraction and isolation

Dried and ground aerial parts of B. pickelii (5400 g) were extracted with ethanol (3 x 10 L, 72 h each) and the crude extract was concentrated to dryness under reduced pressure to yield 190 g of a dark green residue. This material was partitioned with hexane, chloroform, ethyl acetate and butanol. The hexane extract (10 g) was chromatographed over silica gel 60 column (0.063-0.200 mm, Merck) using a gradient of hexane-ETOAc and ETOAc-MeOH. Fractions of 50 mL were collected. The fractions 33-52 were analysed by TLC (SiO2, hexane-ETOAc 9:1), combined and recrystallized with CHCl3:MeOH yielding β-sitosterol (1) (72 mg). Fractions 70-100 were combined after TLC analysis yielding a mixture of sitosterol-3-O-β-D-glucopyranoside (2) and stigmasteryl-3-O-β-D-glucopyranoside (3) (104 mg). The chloroform extract (19 g) was chromatographed on silica gel 60 column (0.063-0.200 mm, Merck) with CHCl3, CHCl3-ETOAc, ETOAc and ETOAc-MeOH. The fraction eluted with CHCl3-ETOAc was also submitted to chromatography over silica gel 60 (0.063-0.200 mm, Merck), using hexane-ETOAc and ETOAc-MeOH as eluent. Fractions of 70 mL were collected and monitored by TLC. Fractions 01-85 combined and chromatographed over Sephadex LH-20 (Pharmacia, Uppsala-Sweden) and eluted with CHCl3:MeOH (50:50, fractions of 20 mL). The fractions 23-24 and 28-34 were combined after observation on TLC (SiO2, CHCl3:MeOH 7:3, FeCl3 5%) and recrystallized with MeOH, leading to the isolation
of vanillic acid (4) (30 mg) and p-coumaric acid (5) (30 mg), respectively. Ethyl acetate extract (3 g) was applied to a Sephadex LH-20 column (Pharmacia, Uppsala-Sweden) with MeOH as eluent, where fractions of 20 mL were obtained. Fractions 07-11 and 12-25 were combined after analysis through TLC (SiO2, CHCl3:MeOH 1:1, FeCl3 5%) and finally recrystallized with MeOH, furnishing quercetin 3-O-β-D-glucopyranoside (isoquercitrin) (6) (40 mg) and kaempferol 3-O-β-D-(6″-E-p-coumaroyl) glucopyranoside (tiliroside) (7) (180 mg), respectively (Figure 1).

Animals

Adult guinea-pigs (Cavia porcellus) of either sex weighing from 300 to 500 g were used in all experiments. The animals were submitted to the following conditions: 12 h light:12 h dark cycle, ventilation and temperature controlled (22 ± 1 ºC) and were deprived of food for 18 h before the beginning of the experiments. The experimental procedure was approved by the Animal Experimentation Committee of the Universidade Federal da Paraíba.

Reagents

NaHCO3, KCl and MgSO4.7H2O (Reagen); acetylcholine, CaCl2.H2O, NaCl, MgCl2.6H2O, NaH2PO4·H2O, glucose (Merck) and histamine (Sigma-Aldrich).

Tissue preparation

To perform in vitro studies, guinea-pig ileum was prepared according to Daniel et al.14. The guinea-pigs were killed by cervical dislocation, the abdomen opened and the ileum was immediately removed. Only the distal portions, with 3 cm length, were used. The tissues were placed in 6 mL isolated organ baths containing modified Krebs solution10 with the following composition (mM): NaCl 117, KCl 4.7, CaCl2 2.5, MgSO4 1.3, NaH2PO4 1.2, NaHCO3 25 and glucose 11, bubbled continuously with a 95% O2 and 5% CO2 gas mixture and maintained at 37 ºC. The pH was adjusted to 7.4 with HCl 1 N. Tension changes were recorded through an isometric force transducer (7003) counterbalanced by 1 g loading, connected with a polygraph (Gemini 7070), both from Ugo Basile (Italy).

At the beginning of each experiment, the reactivity of the ileum was tested with KCl 40 mM. After washout with modified Krebs solution and following 30 min recovery period, contractions were evoked by adding KCl 40 mM, acetylcholine 10-4 M or histamine 10-5 M.

Effect of tiliroside on tonic contractions induced by histamine, acetylcholine or KCl

After resting period, an isometric contraction was elicited in response to histamine 10-5 M, acetylcholine 10-4 M or KCl 40 mM, which provides an 80% of the possible maximum response for each agent (determined from preliminary experiments). Histamine, acetylcholine or KCl remained in contact with the preparation until a contraction plateau was reached (approximately 8 min). After that time the tissue was washed. After a period of 30 min, the process was repeated and on the contraction plateau, tiliroside was added cumulatively. Subsequent concentrations were added only when the response to the previous concentration became stable. Relaxation was expressed as a percentage of decrease of the maximum tension obtained by histamine, acetylcholine or KCl.

**RESULTS AND DISCUSSION**

The structural identifications of the compounds 1-6 were based on spectral analysis and also by comparison with literature data,
which allowed their assignments as β-sitosterol (1)\textsuperscript{21}, a mixture of sitostereryl-3-O-β-D-glucopyranoside (2)\textsuperscript{21} and stigmasteryl-3-O-β-D-glucopyranoside (3),\textsuperscript{3} vanillic acid (4)\textsuperscript{7}, p-coumaric acid (5)\textsuperscript{23} and quercetin-3-O-β-D-glucopyranoside (6) (isosquercitrin)\textsuperscript{24}.

The IR spectrum of compound 7 showed a hydroxyl signal at 3460 cm\textsuperscript{-1}, a conjugated carbonyl ester absorbance at 1685 cm\textsuperscript{-1} and aromatic C=C stretching absorptions at 1607 and 1600 cm\textsuperscript{-1}. The \textsuperscript{1}H NMR spectrum revealed a set of signals of kaempferol, a p-coumarolyl group and a sugar unit. The identity of kaempferol was confirmed by two doublets at δ 6.10 and δ 6.25 (J = 2.5 Hz) for H-6 and H-8 respectively and a pair of doublets at δ 7.96 and δ 6.79 (J = 8.9 Hz) for H-2'.6' and H-3'.5', respectively, corresponding to an AA',BB' system. The p-coumarolyl group was characterized by the presence of A,A',B,B'-type aromatic proton signals at δ 7.26 (2H, d, J = 8.5 Hz) and δ 6.75 (2H, d, J = 8.5 Hz) and two-trans-olefinic hydrogen signals at 6.05 (1H, d, J = 15.6 Hz) and 7.38 (1H, d, J = 15.6 Hz). In the sugar region of the \textsuperscript{1}H NMR spectrum were observed absorptions at δ 3.28-4.31 and also a doublet at δ 5.24 (J = 7.6 Hz) related to the anomeric proton H-1' of glucose. The diaxial coupling (J = 7.6 Hz) between H-1' and H-2' suggested a β-configuration\textsuperscript{25}.

The linkage of the glucose in 7 to the C\textsubscript{6} position of kaempferol was deduced on the basis of the HMBC spectrum analysis, which showed the cross-peak correlation between H-1' (δ 5.24) and C-3 (δ 135.23). The higher field shift of C-6\textsuperscript{″} carbon signal of the glucose moiety compared with kaempferol-3-O-β-D-glucopyranoside\textsuperscript{26} indicated that the p-coumarolyl group might be attached to the C\textsubscript{6}-position of the glucose in 7.

The HMBC spectrum of 7 revealed the correlation of appropriate hydrogen and carbon signals and the /I and J/ correlations observed in the HMBC spectrum proved the unambiguous chemical shifts assignments of carbon atoms and substitution pattern of the molecule (Figure 2) Therefore, compound 7 was identified as kaempferol-3-O-β-D-(6\textsuperscript{″}-E-p-coumarolyl) glucopyranoside.

In the present study, we have investigated the effects of tiliroside on intestinal smooth muscle. The most important finding in this work is the demonstration for the first time that tiliroside exerts a non-selective relaxant action in guinea-pig ileum (data not shown).

Tiliroside, at \textsuperscript{10}\textsuperscript{-4} M has not shown significant inhibitory effect on isotonic contractions induced by \textsuperscript{10}\textsuperscript{-6} M histamine or acetylcholine in guinea-pig ileum. On the other hand, when the ileum was pre-contracted with acetylcholine, histamine or KCl, tiliroside induced a significant relaxant effect in a concentration-dependent manner, as shown in Figure 3.

Independently of the contraction being evoked by either pharmacomechanical (acetylcholine and histamine) or electromechanical (KCl) coupling, the maintenance of the tonic component involves activation of voltage-dependent Ca\textsuperscript{2+} channels\textsuperscript{27}. Therefore, we can postulate that tiliroside could be acting by the blockade of Ca\textsuperscript{2+} influx through these channels to produce non-selective relaxant effects, however further studies will be necessary to reinforce this hypothesis.
