A facile one-step synthesis of 1H-benzoxazine-2,4-diones from heterocyclic anhydrides and TMSA was described. This paper determines their antioxidant activity against nine human bacterial pathogens by the broth microdilution method; antioxidant activity by DPPH• inactivation and a ferric-reducing power assay; and toxicity by a brine shrimp, Artemia salina, assay. The 1H-benzoxazine-2,4-dione yields were in the range of 57 to 98%. The novel compound 1H-pyrazino[2,3-][1,3]oxazine-2,4-dione 4c showed the highest antioxidant capacity (DPPH 35.4% and FRAP 0.063 µmol TEs/µmol).

Keywords: 1H-benzoxazine-2,4-dione; antimicrobial activity; antioxidant activity; toxicity.

INTRODUCTION

Currently, microbial resistance to first-line antibiotic agents is a public health concern, and new drugs are required to treat infected patients. Several heterocyclic structures have shown antibacterial activity, including benzoxazine-2,4-diones.1 Benzoxazine-2,4-diones are potential pharmacophores because of their registered activities: potent inhibitor of hepatitis C virus,2 butyrylcholinesterase inhibitor,3 antiallergic,4 antitumor,5 –antipsychotic,6 antileishmanial,7 and antimonybacterial,8 among others. The syntheses of benzoxazine-2,4-diones from anthranilic acid derivatives,9 isatin,10 allenamides,11 and carbamoylbenzoic acid12 have been reported. Rao et al.13 reported the synthesis of isatoic anhydride from phthalimide and sodium hypochlorite in a basic one-pot solution. This is the only methodology used to produce isatoic anhydride on a large scale. However, if the temperature is not controlled during the course of the reaction, the yield is significantly reduced. In addition, large effluents of wastewater are produced. In general, these processes involve several reaction steps and employ expensive, noncommercial, or dangerous reagents; thus, a better process must be designed.

Viewing the process from a different perspective, there is an increasing interest in compounds with high antioxidant activities, without distillation. Nuclear Magnetic Resonance of 1H(200 MHz) and 13C (50 MHz) spectra were recorded on a Varian Mercury 200 MHz Spectrometer in DMSO-d6 with TMS as an internal standard. Chemical ionization mass spectra were obtained with a Varian Titan 4000 ion trap GC-MS, and the intensities were reported as a percentage relative to the base peak after the corresponding m/z value. HR-MS was recorded on an ESI/APCI-TOF Bruker model MicroTOF-II-FocusTM at the Universidad Autónoma Metropolitana, Campus Iztapalapa. Infrared spectra were recorded on a Cary 660 series FTIR-ATR spectrophotometer. Melting points were obtained on a Stuart apparatus model SMP30; the reported value is the average of three separate experiments.

General procedure for the synthesis of benzoxazine-2,4-diones

The heterocyclic anhydride in THF (1.0 mM) and trimethylsilylazide (TMSA, 1.05 equiv.) were stirred in a Schlenk bulb for 17 h at 53 °C, then temperature was increased to reflux and maintained for 2 h. The resulting solution was concentrated under vacuum pressure until a solid was formed. The solid was washed with diethyl ether (5 x 4 mL) to obtain 1H-benzoxazine-2,4-diones in high purity.

1H-3,1-benzoxazine-2,4-quinone (4a). (For full characterization see lit.20–22 CAS number: 118-48-9; yield 85%; white solid; Rf 0.58 (petroleum ether/EtOAc: 1:1 v/v)); 1H-NMR (200 MHz, DMSO-d6): δ 11.74 (br s, 1H), 7.91 (dd, J1=8.07, J2=1.1 Hz, 1H), 7.74 (dd, J3,J4=7.99, 1H, δ 1.28 Hz, 1H), 7.25 (m, 2H); 13C-NMR (50 MHz, DMSO-d6): δ 159.9, 147.1, 141.4, 136.9, 128.9, 123.5, 115.3; CG-MS m/z: 164 [M+H]+

EXPERIMENTAL

Chemistry

All reagents were purchased in the highest quality available and were used without further purification. The solvents used in column chromatography were obtained from commercial suppliers and used without distillation. Nuclear Magnetic Resonance of 1H(200 MHz) and 13C (50 MHz) spectra were recorded on a Varian Mercury 200 MHz Spectrometer in DMSO-d6 with TMS as an internal standard. Chemical ionization mass spectra were obtained with a Varian Titan 4000 ion trap GC-MS, and the intensities were reported as a percentage relative to the base peak after the corresponding m/z value. HR-MS was recorded on an ESI/APCI-TOF Bruker model MicroTOF-II-FocusTM at the Universidad Autónoma Metropolitana, Campus Iztapalapa. Infrared spectra were recorded on a Cary 660 series FTIR-ATR spectrophotometer. Melting points were obtained on a Stuart apparatus model SMP30; the reported value is the average of three separate experiments.

The FRAP reagent was prepared by mixing 2.5 mL of 10 mM 2,4,6-tripyridyl-s-triazine (TPTZ), 2.5 mL of 40 mM HCl, 2.5 mL of 20 mM FeCl₃, and 25 mL of 0.3 M NaCl (w/v) and density adjusted to 1000 ft/mL. The ferric-reducing power assay was performed as described by Sarmiento-Sánchez et al. with slight modifications. The DPPH* scavenging activity of the benzoxazine-2,4-dione was calculated as follows:

DPPH scavenging effect (%): \( \% = \frac{A_C - A_T}{A_C} \times 100 \)

where \( A_C \) is the absorbance of the control and \( A_T \) is the absorbance in the presence of the 1H-benzoxazine-2,4-diones (or the positive control, TROLOX) at 100 µg mL⁻¹. Calculated values correspond to the mean ± one standard deviation of one experiment in quadruplicate and were determined by SPSS Statistics software v19 (IBM company).

**Ferric-reducing antioxidant power (FRAP) assay**

The ferric-reducing power assay was performed as described by Zhang et al. with slight modifications. The FRAP reagent was prepared by mixing 2.5 mM of 10 mM 2,4,6-tripyridyl-s-triazine (TPTZ), 2.5 mL of 40 mM HCl, 2.5 mL of 20 mM FeCl₃, and 25 mL of 0.3 M NaCl (w/v). For the blank or compound assay, 1.95 mL of the freshly prepared FRAP reagent was mixed with ethanol (0.05 mL) or with the benzoxazine-2,4-dione (0.05 mL, 50 µg mL⁻¹). The mixture was incubated in darkness conditions (37 °C, 5 min), and the absorbance was measured at 593 nm. In the FRAP assay, the blue-colored Fe(III)-tripyridyltriazine compound was oxidized to the colorless Fe(III) form. Calculated values were the mean of four replicates and were reported as µmol of Trolox equivalents (µmol TE/µmol of compound) in accordance with the equation of the Trolox calibration curve:

\[ \text{Absorbance} = 19.57 \text{ Trolox (µmol)} + 0.1051 \]

\( (r^2 = 0.9928) \)

**Bacteria and the antibacterial assay**

Activity against nine human bacterial pathogens was evaluated; two strains were ATCC (DIFCO Laboratories, MI, U.S.A.) (i.e., Staphylococcus aureus 29213 and Escherichia coli 25922), and seven clinical isolates were provided by the bacteriology laboratory of the Instituto Nacional de Pediatría, Secretaría de Salud en Mexico, D.F. (i.e., Streptococcus group A-4, Staphylococcus aureus 3, E. coli AO11, E. coli AO19, Salmonella typhi, and Shigella dysenteriae). For the antibacterial activity evaluation, the benzoxazine-2,4-diones were dissolved in aqueous DMSO (5% v/v) and evaluated at the following concentrations: 3.125, 6.25, 12.5, 25, 50, 100, 200, 225, 250, 275, 300, 350, and 400 µg mL⁻¹. The antibacterial activity was determined by a microdilution assay in 96-well plates.

Strains were cultured in Petri dishes (TSA, trypticase soy agar) for 18–20 h at 37 °C; two to five colonies were suspended in 1.0 mL of 0.85% NaCl (w/v) and density adjusted to 10⁶ CFU mL⁻¹ (0.5 McFarland value). Bacterial cultures (50 µL, 10⁶ CFU mL⁻¹) and 50 µL of each compound/concentration were mixed in the wells. Gentamicin (0.5, 1, 2, 4, 8, 16, and 32 µg mL⁻¹) was used as a positive control, microorganisms without additives as a negative control, and dissolving solvents without compounds as a toxicity control. The 96-well plates were incubated for 18–20 h at 37 °C.

**Brine shrimp lethality bioassay**

The toxicities of the benzoxazine-2,4-diones were evaluated by the brine shrimp larvae assay. Dried brine shrimp eggs were incubated in a saline medium under light conditions for 48 h. One-day-old larvae (10–12 per vial in 100 µL of saline solution) were transferred into 96-well plates and exposed to 100 µL of the benzoxazine-2,4-diones at 100, 300, 500, 700, and 1000 µg mL⁻¹. Four replicates of
each concentration were done. The dead larvae were counted after 24 h of incubation, and the Median Lethal Concentration ($LC_{50}$) and 95% confidence intervals were determined by probit analysis with SPSS Statistics software v19 (IBM company). Evaluated compounds were classified by the $LC_{50}$ values as follows: $LC_{50} \geq 1000 \mu g mL^{-1}$, classified as non-toxic; $100 < LC_{50} < 1000$, classified as moderately toxic; and $10 < LC_{50} < 100$, classified as very toxic.

**RESULTS AND DISCUSSION**

**Chemistry**

As depicted in Figure 1, the synthesis of the 1H-benzoxazine-2,4-diones involved an acylazide intermediate 2, followed by a subsequent Curtius rearrangement to generate an isocyanate 3, and an intramolecular cyclization to provide the benzoxazine-2,4-diones 4. At first, the reaction conditions were optimized following the synthesis of the benzoxazine-2,4-dione 4a: the initial conditions were those recommended by Washburne, the starting materials were refluxed in benzene for 19 h, and the reaction product was detected by GC-MS in positive chemical ionization. Later, the reaction conditions were changed: temperatures were $53 \ ^\circ C$ for the first 17 h, followed by $85 \ ^\circ C$ for 2 h, resulting in isolation of the compound 4a with 54% yield and high purity. The same conditions were used for the synthesis of 4a employing acetonitrile, benzene-acetonitrile (4:1 v/v), DMSO, and THF as solvents. Some unidentified byproducts were detected with acetonitrile and DMSO as solvents. In contrast, yields were high for the reactions with THF (85%) and benzene-acetonitrile 4:1 v/v (50%). The higher yield for THF could be associated with the solubility of reagents and intermediates in this solvent. Washburne reported that oxazine-2,6-diones were obtained as silylated products. However, silylated benzoxazine-2,4-diones were not detected under our modified reaction conditions. The benzoxazine-2,4-diones synthesis using heterocyclic anhydrides and TMSA has the following advantages: i) reaction conditions are simple, ii) the products are obtained in good yields, and iii) less waste is produced in comparison with the phthalimides method.

**The benzoxazine-2,4-dione yields were similar to those reported**

</tbody>
</table>

$^a$Isomers ratio were obtained by $^1$H-NMR of the isomers mixture.

Table 2 shows the regioisomeric distribution of benzoxazine-2,4-diones resulting from the formation of non-symmetric heterocyclic anhydrides. The 7-isomer was always detected, ranging from 23% (R = F) to 47% (R = CH$_2$); thus, the regioselectivity in the benzoxazine-2,4-dione synthesis resulted from a combination of electronic and steric effects. A similar phenomenon was registered for the aryloxazine-2,6-dione synthesis.

The electronic effect is clear when contrasting the carbonyl in position 1 was more electropositive than that in position 2 by the effect of the fluorine atom attached at position 4 ($4f$).

### Antioxidant, antibacterial, and toxicity activities

All of the synthetic benzoxazine-2,4-diones acted as reducing agents over the DPPH radical, with $4d$ and $4e$ as the best antioxidants (Table 1). Based on the structure-activity analysis, antioxidant activity can be associated with substitutions of the aromatic ring; the carbonyl in position 2 by the effect of the fluorine atom attached at position 4 ($4f$). The activity can be associated with substitutions of the aromatic ring; the carbonyl in position 2 by the effect of the fluorine atom attached at position 4 ($4f$).

The toxicity of the aromatic ring; the carbonyl in position 2 by the effect of the fluorine atom attached at position 4 ($4f$). The activity can be associated with substitutions of the aromatic ring; the carbonyl in position 2 by the effect of the fluorine atom attached at position 4 ($4f$). The activity can be associated with substitutions of the aromatic ring; the carbonyl in position 2 by the effect of the fluorine atom attached at position 4 ($4f$).

### CONCLUSION

The proposed one-step method produced 1H-benzoxazine-2,4-diones from heterocyclic anhydrides with TMSA in good yields and with high purity. This methodology is simple, and the starting materials are economic, accessible, and commercial. The 1H-pyrazino[2,3-d][1,3]oxazine-2,4-dione $4e$ showed the highest antioxidant activity for the two methods tested (DPPH radical scavenging and ferric-reducing power).
